How can your information be kidnapped?

Ransomware is a malicious computer program that kidnaps important information on your computer and holds it hostage until you pay a ransom to get it back.

You receive a regular email with an "harmless" photo, PDF or word file. When you **open the attached file**, everything's fine! Or so it seems...

You try to look at your photos, but you can't. You want to edit a document, but you can't even open it. Uh oh! Ransomware is already in your system.

The only thing you can see is a window asking you to pay a ransom. It coerces you with the remaining time and offers you discounts if you pay immediately.

But... you're already infected and paying to retrieve the stolen data does not really mean that it will be freed, or that it won't happen again.

This is why it is so important to protect your system with a cybersecurity solution that's capable of detecting and blocking advanced attacks like this one.
